

## Problems of Chapter 2

Wednesday, September 16, 2020 8:35 PM

- A semigroup is a set  $S$  with binary operation  $o: S \times S \rightarrow S$  which is associative,  $a o (b o c) = (a o b) o c$ . First observe that  $a^n = a o a^{n-1}$  by induction and is also  $a^{n-1} o a$  by associativity.

To prove (2.2):  
 $a^n o a^m = (a^{n-1} o a) o a^m = a^{n-1} o (a o a^m) = a^{n-1} o (a^{m+1})$ . Then prove by induction that  $a^n o a^m = a^{n+m}$ .

To prove (2.3):  
 $(a o b)^n = a^n o b^n$ . Follow on similar lines by splitting  $a^n = a o a^{n-1}$  then by associativity.
- An operation on  $\{0,1\}$  is any binary Boolean function. Binary means of two variables. We can then have for any one such function  
 $f(0,0)=a, f(0,1)=b, f(1,0)=c, f(1,1)=d$  where  $a,b,c,d$  are 0 or 1. There are  $2^4=16$  such functions. Now check which of these satisfy associativity. Then that function gives a semigroup.

For example the function  
 $F(0,0)=1, f(0,1)=1, f(1,0)=0, f(1,1)=0$  is not associative,  
 $((0,0),1)=(1,1)=0$  while  $(0,(0,1))=(0,1)=1$
- If  $e_1$  and  $e_2$  are two neutral elements then by definition  $e_1 o e_2 = e_1 = e_2$ .
- After finding out all functions which form semigroups of  $\{0,1\}$ , check for existence of identity element to discover monoids. For a group all elements must have inverses.
- If  $a o b = e$  and  $a o c = e$  then  $a^{-1} o (a o b) = a^{-1} o (a o c)$  gives  $b = c$ .
- The map given as  $\mathbb{Z}/m \rightarrow \mathbb{Z}/n$  takes  $a \bmod m$  to  $a \bmod n$ . But as  $n < m$ ,  $a \bmod m = a \bmod n$ . The map respects sums  $(a+b) \bmod m = (a \bmod m + b \bmod m) \bmod m$  and  $ab \bmod m = (a \bmod m)(b \bmod m) \bmod m$  hence the map is a homomorphism. For any element  $a$  in  $\mathbb{Z}/n$  there is at least one preimage  $a$  itself in  $\mathbb{Z}/m$ . Hence it is surjective.

7. Consider  $\mathbb{Z}/4=\{0,1,2,3\}$ . Then  $2 \cdot 3 = 2 \cdot 1$  but 3 is not equal to 1. Hence cancellation does not hold. (in general in  $\mathbb{Z}/m$  there are zero divisors which are not invertible hence cannot be cancelled).
8.  $\mathbb{Z}/16=\{0,1,2,\dots,15\}$ . Invertible elements are (coprime to 2), hence all odd numbers  $\{1,3,5,\dots,15\}$  this is the group of units  $(\mathbb{Z}/16)^\times$ . Zero divisors are  $\{2,4,6,8,\dots,14\}$ .
9. If  $R$  is a ring and  $R^\times$  the set of invertible elements with product  $\circ$  as binary operation, then  $\circ$  is associative, there is the unit element 1 and every element is invertible. Hence  $(R^\times, \circ)$  is a group.
10.  $122x \equiv 1 \pmod{343}$ . Find  $d = \gcd(343, 122) = 1$ . Then by extended Euclid find  $a, b$  such that  $122x + 343y = 1$ . If  $\gcd$  is not 1 then there is no solution.
11.  $ax \equiv b \pmod{m}$  iff  $ax + qm = b$  hence soln exists iff  $\gcd(a, m) \mid b$ . Let the  $\gcd$  be  $d$ . Then for  $a = da_1$ ,  $m = dm_1$ ,  $a_1, m_1$  are coprime. Hence by ext Euclid you have  $a_1x + m_1y = 1$  find all such  $x, y$ . Then  $ax \equiv d \pmod{m}$ .
12. High school problem.
13. Invertible elements of  $\mathbb{Z}/25$  are elements coprime to 5. Hence  $\{1, 2, 3, 4, 6, 7, 8, 9, 11, \dots, 24\}$  find their inverses mod 25. For example  $2 \cdot 13 \equiv 1 \pmod{25}$ ,  $3 \cdot 17 \equiv 51 \equiv 1 \pmod{25}$ .
14. Easy exercise. Show that  $\text{lcm}(a, b) \gcd(a, b) = ab$ .
15. Set theory pigeon whole principle. Or simply replace each element of  $X$  by the image in  $Y$ . Then you have  $|X| \leq |Y|$  and  $|Y| \leq |X|$  hence they are equal. Is this true for infinite sets?
16. Subgroup generated by powers of 2 in  $\mathbb{Z}/17$ .  $\{1, 2, 4, 8, 16\}$ .
17. Prime factors of  $1234 = 2 \cdot 617$ . 617 is prime. Hence order 2 must be either 617 or 1234.
18. Compute orders.

19.  $2^{20} \bmod 7 = 2^{(20 \bmod 6)} \bmod 7$  by Fermat's little theorem.  
Hence  $2^{20} \bmod 7 = 2^2 \bmod 7 = 4$ .
20. Proved in class notes.
21. Given  $p \equiv 3 \pmod{4}$  and there is  $x$  such that  $a = x^2 \pmod{p}$ .  
Then  $(p+1) \equiv 0 \pmod{4}$  hence  $b = a^{(p+1)/4} \pmod{p}$  is defined.  
If  $p \mid a$  then the result is trivial. So assume  $p$  does not divide  $a$ . Then  $b^4 = a^{(p+1)} \pmod{p} = a^2 \pmod{p}$  by Fermat's theorem. Hence we have  $(b^2 + a)(b^2 - a) = 0 \pmod{p}$  which shows that  $b^2 = \pm a \pmod{p}$  i.e.  $b$  is a square root of  $a \pmod{p}$ .
22. Proof by construction. Done in previous class.
23. First note that 1237 is prime. Then find a primitive root  $z$  of  $\mathbb{Z}/1237$ . Then use the formula  $\text{ord}(z)^k = 1236 / \gcd(k, 1236) = 103$ . From this compute  $k$  after computing prime factorization of 1236.
24.  $G$  is cyclic group of order  $n$  and  $g$  is a primitive element, then all powers of  $g$  generate  $G$ . The homomorphism is  $g^{(x+y) \bmod n} = g^x g^y$ . For each  $x$  in  $\mathbb{Z}/n$  there is a unique power of  $g$  in  $G$  hence this is an isomorphism.
25.  $X = [(3.5.7)(3.5.7)^{-1} \bmod 2 + (2.5.7)(2.5.7)^{-1} \bmod 3 + (2.3.7)(2.3.7)^{-1} \bmod 5 + (2.3.5)(2.3.5)^{-1} \bmod 7] \bmod 2.3.5.7 = 1+1+2.3+2.4=16$
26. Divide and check by irreducible polynomials of deg 3,4,5.
27. Search over  $p$ . May need lot of computation.
28. Group of finite field  $F_5$  has 4 elements. Hence all irreducible polynomials of degree 5 which generate the field whose groups are all the required groups.
